1 The C Programming Language

I can clearly C why you'd want to use C. Already sorry in advance for all the bad C jokes that are going to be part of this section

C is a compiled, low-level programming language, lacking many features modern high-level programming languages offer, like Object Oriented programming, true Functional Programming (like Haskell implements), Garbage Collection, complex abstract datatypes and vectors, just to name a few. (It is possible to replicate these using Preprocessor macros, more on this later).

On the other hand, it offers low-level hardware access, the ability to directly integrate assembly code into the .c files, as well as bit level data manipulation and extensive memory management options, again just to name a few.

This of course leads to C performing excellently and there are many programming languages whose compiler doesn't directly produce machine code or assembly, but instead optimized C code that is then compiled into machine code using a C compiler. This has a number of benefits, most notably that C compilers can produce very efficient assembly, as lots of effort is put into the C compilers by the hardware manufacturers.

There are many great C tutorials out there, a simple one (as for many other languages too) can be found here

1.1 Basics

C uses a very similar syntax as many other programming languages, like Java, JavaScript and many more...to be precise, it is *them* that use the C syntax, not the other way around. So:

File: 00_intro.c

```c
// This is a line comment
/* this is a block comment */
#include "01_func.h" // Relative import

int i = 0; // This allocates an integer on the stack

int main( int argc, char *argv[] ) {
    // This is the function body of a function (here the main function)
    // which serves as the entrypoint to the program in C and has arguments
    printf( "Argc: %d\n", argc );     // Number of arguments passed, always >= 1
                                      // (first argument is the executable name)
    for ( int i = 0; i < argc; i++ ) // For loop just like any other sane programming language
        printf( "Arg %d: %s\n", i, argv[ i ] ); // Outputs the i-th argument from CLI

    get_user_input_int( "Select a number" ); // Function calls as in any other language
    return 0;                                // Return a POSIX exit code
}
```

In C we are referring to the implementation of a function as a ***(function) definition*** (correspondingly, *variable definition*, if the variable is initialized) and to the definition of the function signature (or variables, without initializing them) as the ***(function) declaration*** (or, correspondingly, *variable declaration*).

C code is usuallt split into the source files, ending in .c (where the local functions and variables are declared, as well as all function definitions) and the header files, ending in .h, usually sharing the filename of the source file, where the external declarations are defined. By convention, no definition of functions are in the .h files, and neither variables, but there is nothing preventing you from putting them there.

File: 01_func.h

```c
#include <stdio.h> // Import from system path
                   // (like library imports in other languages)

int get_user_input_int( char prompt[] );
```

1.1.1 Control Flow

Many of the control-flow structures of `C` can be found in the below code snippet. A note of caution when using goto: It is almost never a good idea (can lead to unexpected behaviour, is hard to maintain, etc). Where it however is very handy is for error recovery (and cleanup functions) and early termination of multiple loops (jumping out of a loop). So, for example, if you have to run multiple functions to set something up and one of them fails, you can jump to a label and have all cleanup code execute that you have specified there. And because the labels are (as in Assembly) simply skipped over during execution, you can make very nice cleanup code. We can also use `continue` and `break` statements similarly to `Java`, they do not however accept labels. (Reminder: `continue` skips the loop body and goes to the next iteration)

File: `01_func.c`

```c
#include "01_func.h"
#include <stdio.h>

int get_user_input_int( char prompt[] ) {
    int input_data;
    printf( "%s", prompt );           // Always wrap strings like this for printf
    scanf( "%d", &input_data );       // Get user input from CLI
    int input_data_copy = input_data; // Value copied

    // If statements just like any other language
    if ( input_data )
        printf( "Not 0" );
    else
        printf( "Input is zero" );

    // Switch statements just like in any other language
    switch ( input_data ) {
        case 5:
            printf( "You win!" );
            break; // Doesn't fall through
        case 6:
            printf( "You were close" ); // Falls through
        default:
            printf( "No win" ); // Case for any not covered input
    }

    while ( input_data > 1 ) {
        input_data -= 1;
        printf( "Hello World\n" );
    }

    // Inversed while loop (executes at least once)
    do {
        input_data -= 1;
        printf( "Bye World\n" );
        if ( input_data_copy == 0 )
            goto this_is_a_label;
    } while ( input_data_copy > 1 );

this_is_a_label:
    printf( "Jumped to label" );
    return 0;
}
```

1.1.2 Declarations

We have already seen a few examples for how C handles declarations. In concept they are similar (and scoping works the same) to most other C-like programming languages, including Java.

File: 02_declarations.c

```c
int my_int;                // Allocates memory on the stack.
                           // Variable is global (read / writable by entire program)
static int my_local_int; // only available locally (in this file)
const int MY_CONST = 10; // constant (immutable), convention: SCREAM_CASE

enum { ONE, TWO } num; // Enum. ONE will get value 0, TWO has value 1

enum { O = 2, T = 1 } n; // Enum with values specified

// Structs are like classes, but contain no logic
struct MyStruct {
        int el1;
        int el2;
};

int fun( int j ) {
    static int i = 0;              // Persists across calls of fun
    short my_var = 1;              // Block scoped (deallocated when going out of scope)
    int my_var_dbl = (int) my_var; // Explicit casting (works between almost all types)
    return i;
}

int main( int argc, char *argv[] ) {
    if ( ( my_local_int = fun( 10 ) ) ) {
        // Every c statement is also an expression, i.e. you can do the above!
    }
    struct MyStruct test;            // Allocate memory on stack for struct
    struct MyStruct *test_p = &test; // Pointer to memory where test resides
    test.el1 = 1;                    // Direct element access
    test_p->el2 = 2;                 // Via pointer
    return 0;
}
```

A peculiarity of C is that the bit-count is not defined by the language, but rather the hardware it is compiled for.

C data type	typical 32-bit	ia32	x86-64
`char`	1	1	1
`short`	2	2	2
`int`	4	4	4
`long`	4	4	8
`long long`	8	8	8
`float`	4	4	4
`double`	4	8	8
`long double`	8	10/12	16

Table 1.1: Comparison of byte-sizes for each datatype on different architectures

By default, integers in C are `signed`, to declare an unsigned integer, use `unsigned int`. Since it is hard and annoying to remember the number of bytes that are in each data type, C99 has introduced the extended integer types, which can be imported from stdint.h and are of form int<bit count>_t and uint<bit count>_t, where we substitute the <bit count> with the number of bits (have to correspond to a valid type of course).

Another notable difference of C compared to other languages is that C doesn't natively have a boolean type, by convention a short is used to represent it, where any non-zero value means true and 0 means false. Since boolean types are quite handy, the ! syntax for negation turns any non-zero value of any integer type into zero and vice-versa. C99 has added support for a bool type via stdbool.h, which however is still an integer.

Notably, C doesn't have a very rigid type system and lower bit-count types are implicitly cast to higher bit-count data types, i.e. if you add a short and an int, the short is cast to short (bits 16-31 are set to 0) and the two are added. Explicit casting between almost all types is also supported. Some will force a change of bit representation, but most won't (notably, when casting to and from float-like types, minus to void)

Another important feature is that every C statement is also an expression, see above code block for example.

The void type has ***no*** value and is used for untyped pointers and declaring functions with no return value

1.1.3 Operators

The list of operators in C is similar to the one of Java, etc. In Table 1.2, you can see an overview of the operators, sorted by precedence in descending order. You may notice that the & and * operators appear twice. The higher precedence occurrence is the address operator and dereference, respectively, and the lower precedence is bitwise and and multiplication, respectively.

Very low precedence belongs to boolean operators && and ||, as well as the ternary operator and assignment operators

Operator	Associativity
() [] -> .	Left-to-right
! ~ ++ -- + - * & (type) sizeof	Right-to-left
* / %	Left-to-right
+ -	Left-to-right
<< >>	Left-to-right
< <= >= >	Left-to-right
== !=	Left-to-right
& (logical and)	Left-to-right
^ (logical xor)	Left-to-right
| (logical or)	Left-to-right
&& (boolean and)	Left-to-right
|| (boolean or)	Left-to-right
? : (ternary)	Right-to-left
= += -= *= /= %= &= ^=—= <<= >>=	Right-to-left
,	Left-to-right

Table 1.2: C operators ordered in descending order by precedence

Associativity

- Left-to-right: $A + B + C \mapsto (A + B) + C$
- Right-to-left: A += B += C $\mapsto$ (A += B) += C

As it should be, boolean and, as well as boolean or support early termination.

The ternary operator works as in other programming languages result = expr ? res_true : res_false;

As previously touched on, every statement is also an expression, i.e. the following works

```
printf("%s", x = foo(y)); // prints output of foo(y) and x has that value
```

Pre-increment (++i, new value returned) and post-increment (i++, old value returned) are also supported by C.

1.1.4 Arrays

`C` compiler does not do any array bound checks! Thus, always check array bounds. Unlike some other programming languages, arrays are ***not*** dynamic length.

The below snippet includes already some pointer arithmetic tricks. The variable `data` is a pointer to the first element of the array.

File: `03_arrays.c`

```c
#include <stdint.h>
#include <stdio.h>

int main( int argc, char *argv[] ) {
    int data[ 10 ];                      // Initialize array of 10 integers
    data[ 5 ] = 5;                       // element 5 is now 5
    *data = 10;                          // element 0 is now 5
    printf( "%d\n", data[ 0 ] );      // print element 0 (prints 10)
    printf( "%d\n", *data );          // equivalent as above
    printf( "%d\n", data[ 5 ] );      // print element 5 (prints 5)
    printf( "%d\n", *( data + 5 ) ); // equivalent as above
    int multidim[ 5 ][ 5 ];              // 2-dimensional array
                                         // We can iterate over it using two for-loops
    return 0;
}
```

2 x86 Assembly
